### Human sexual selection

In general, New World primates showed little sexual dimorphism in F 0, averaging a mean F 0 dimorphism (male F 0 /female F 0) of 1.05 across seven species, whereas male cercopithecines averaged half of the F 0 of females (mean F 0 dimorphism = 0.48 across 10 species).

In response to this sexual selection for good sperm, male chimpanzees have evolved large testicles, copious ejaculates, and high sperm counts. Female primates face a trade-off. They can select for the best-swimming sperm by mating very promiscuously, or they can select for the best courtship behavior by mating very selectively.

Sexual selection in humans concerns the concept of sexual selection, introduced by Charles Darwin as an element of his theory of natural selection, as it affects humans. Sexual selection is a biological way one sex chooses a mate for the best reproductive success. Most compete with others of the same sex for the best mate to contribute their genome for future generations.

Sexual Selection and the Evolution of Brain Size in Primates

The evolution of brain size and complexity in the Order Primates has been widely regarded as the hallmark of primate evolutionary history. Despite their importance to our understanding of primate evolution, the relationship between sexual selection and the evolutionary development of brain size is not well studied.
